**WHY DO WE HAVE TO  
EVALUATE THE ARTERIAL  
FUNCTION?**

# LIMITATIONS OF CV RISK SCORING

# Limitations of traditional risk scores (SCORE, Framingham)

- They do not consider several established risk factors (obesity, diabetes, history of premature CHD in first degree relatives, lack of regular physical exercise, psychosocial factors, etc.)
- They are mainly focused on fatal and non-fatal CHD, however ischemic stroke is also a major cause of deaths and disability
- They do not consider the ethnicity
- More than 80% of the global CVD burden is in low-income and middle-income countries where the value of risk factors has not yet been established

Simon, A. and Levenson, J.:

*May subclinical arterial disease help to better detect and treat high-risk asymptomatic individuals?*

*J Hypertens* 2005, 23: 1939-1945

**„....although traditional risk factors may account for 90% of the attributable cardiovascular risk, their prediction of CVD is weak probably because the susceptibility to CVD varies greatly among individuals.”**

**„The detection of high CVD risk based on traditional risk factors alone probably fails to diagnose a number of high-risk conditions and therefore measurement of new potential risk factors has been proposed to improve the detection of high-risk asymptomatic subjects.”**

*Simon, A. and Levenson, J.:*

*May subclinical arterial disease help to better detect and treat high-risk asymptomatic individuals?*

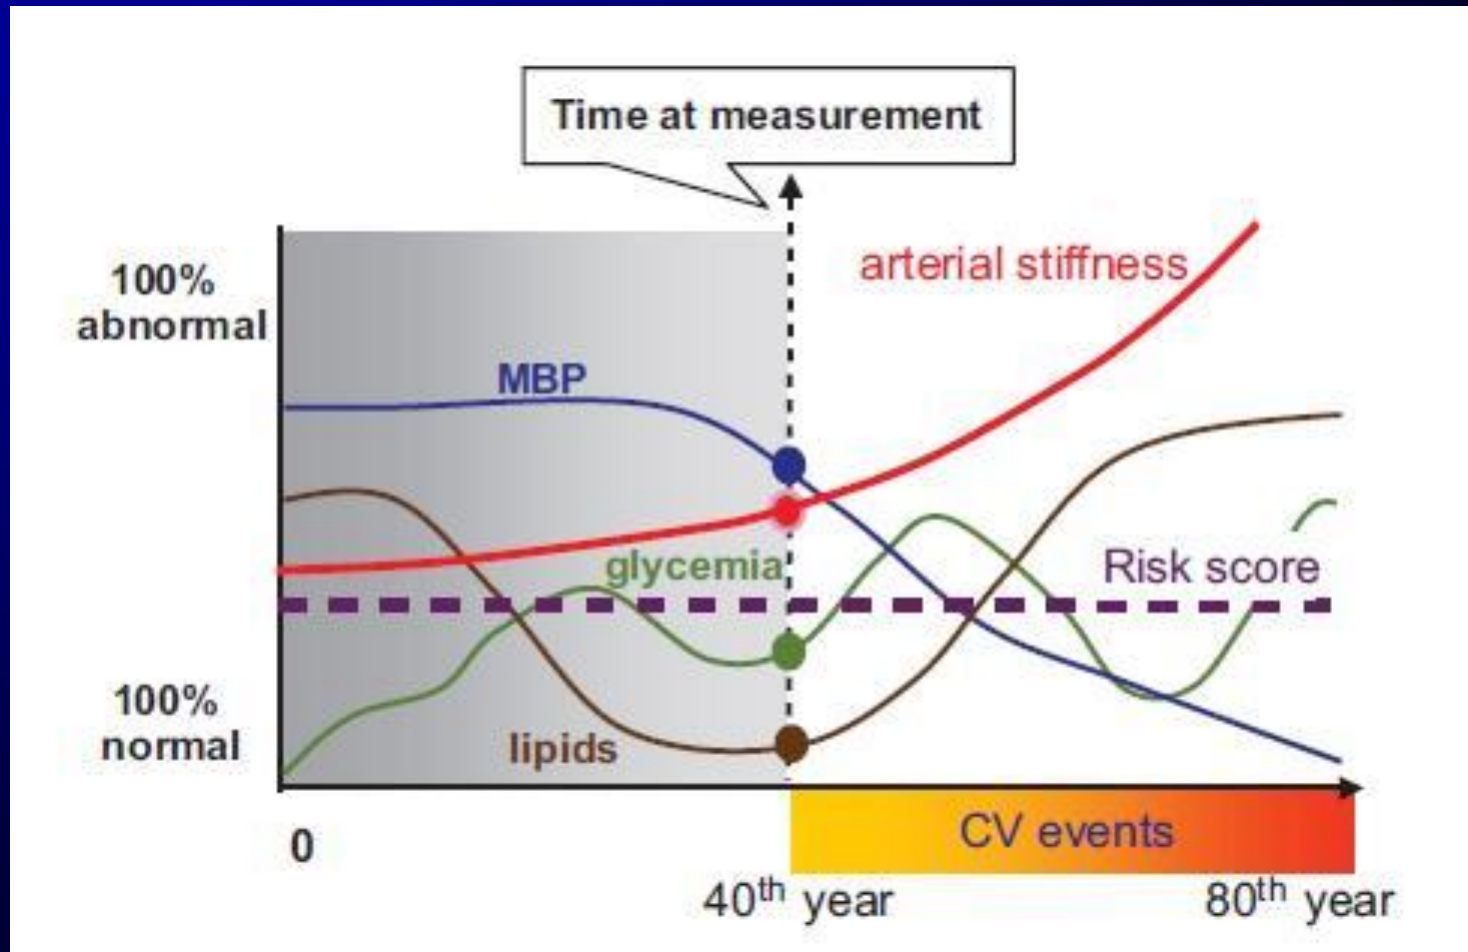

*J Hypertens 2005, 23: 1939-1945*

„.....vascular stiffness precedes atherosclerosis and is a risk factor for atherosclerosis.

.....studies clearly demonstrate that **PWV** and the **augmentation index** are associated with the structural changes of atherosclerosis”

# Arterial Stiffness, Wave Reflections, and the Risk of Coronary Artery Disease

Thomas Weber, MD; Johann Auer, MD; Michael F. O'Rourke, MD; Erich Kvas, ScD; Elisabeth Lassnig, MD; Robert Berent, MD; Bernd Eber, MD

**Background**—Increased arterial stiffness, determined invasively, has been shown to predict a higher risk of coronary atherosclerosis. However, invasive techniques are of limited value for screening and risk stratification in larger patient groups.

**Methods and Results**—We prospectively enrolled 465 consecutive, symptomatic men undergoing coronary angiography for the assessment of suspected coronary artery disease. Arterial stiffness and wave reflections were quantified noninvasively using applanation tonometry of the radial artery with a validated transfer function to generate the corresponding ascending aortic pressure waveform. Augmented pressure (AP) was defined as the difference between the second and the first systolic peak, and augmentation index (AIx) was AP expressed as a percentage of the pulse pressure. In univariate analysis, a higher AIx was associated with an increased risk for coronary artery disease (OR, 4.06 for the difference between the first and the fourth quartile [1.72 to 9.57;  $P < 0.01$ ]). In multivariate analysis, after controlling for age, height, presence of hypertension, HDL cholesterol, and medications, the association with coronary artery disease risk remained significant (OR, 6.91;  $P < 0.05$ ). The results were exclusively driven by an increase in risk with premature vessel stiffening in the younger patient group (up to 60 years of age), with an unadjusted OR between AIx quartiles I and IV of 8.25 ( $P < 0.01$ ) and a multiple-adjusted OR between these quartiles of 16.81 ( $P < 0.05$ ).

**Conclusions**—AIx and AP, noninvasively determined manifestations of arterial stiffening and increased wave reflections, are strong, independent risk markers for premature coronary artery disease. (*Circulation*. 2004;109:184-189.)

**Key Words:** coronary disease ■ waves ■ arteries ■ arteriosclerosis

# Central (aortic) SBP

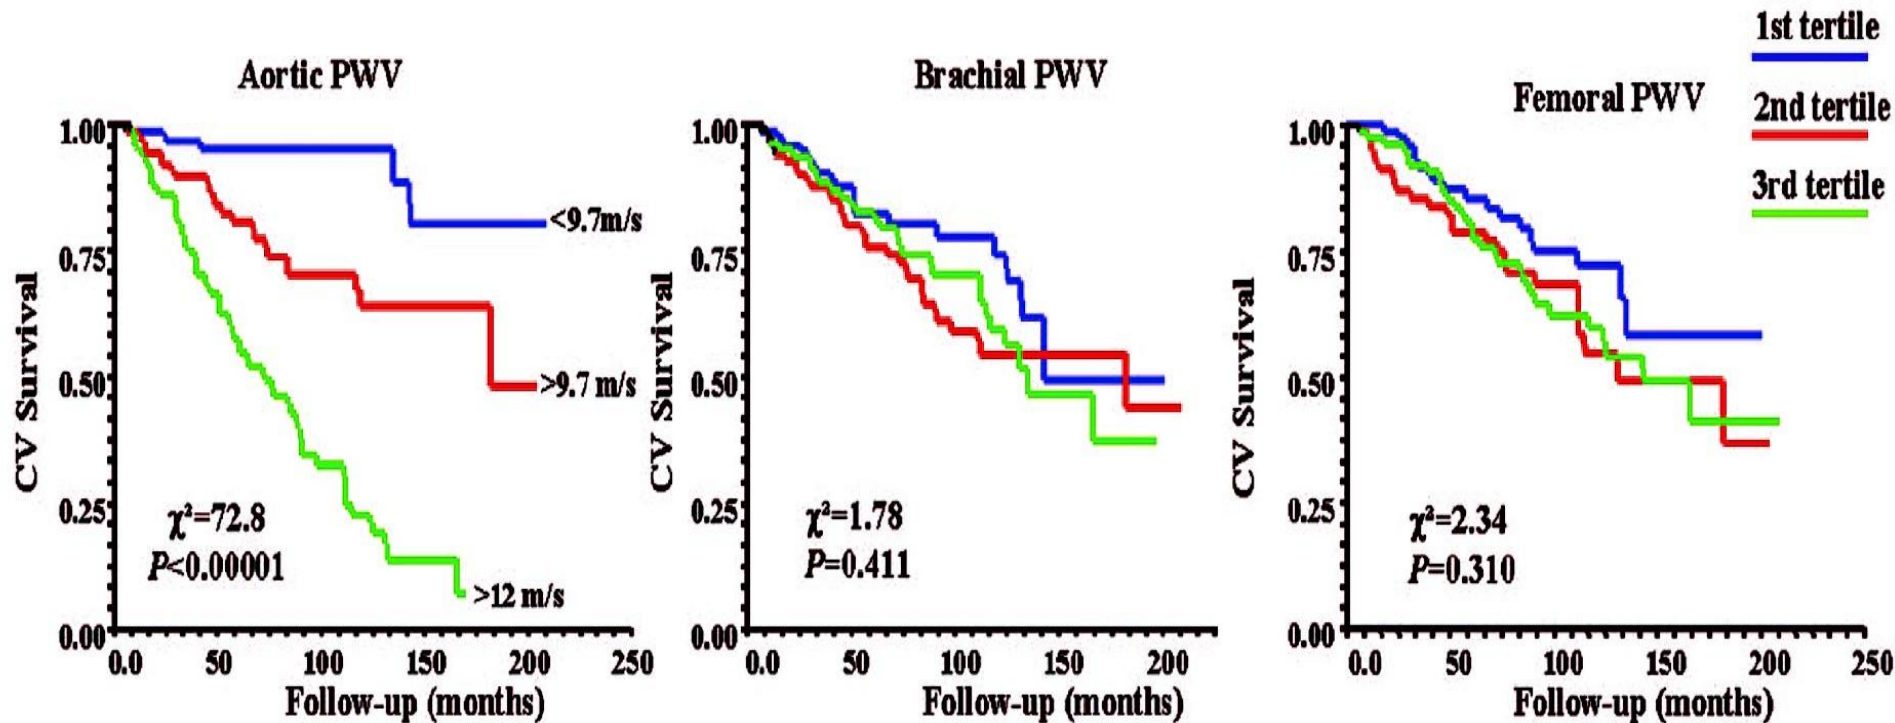

## Central Pressure More Strongly Relates to Vascular Disease and Outcome Than Does Brachial Pressure

### The Strong Heart Study

Mary J. Roman, Richard B. Devereux, Jorge R. Kizer, Elisa T. Lee, James M. Galloway, Tauqeer Ali, Jason G. Umans, Barbara V. Howard

**Abstract**—Brachial blood pressure is predictive of cardiovascular outcome; however central pressure may better represent the load imposed on the coronary and cerebral arteries and thereby bear a stronger relationship to vascular damage and prognosis. Relations of brachial and central pressures to carotid artery hypertrophy (intimal-medial thickness and vascular mass), extent of atherosclerosis (plaque score), and incident cardiovascular events were examined in the Strong Heart Study. Central pressures were calculated using radial applanation tonometry. Among 3520 participants, central and brachial pulse pressures were more strongly related to vascular hypertrophy and extent of atherosclerosis than were systolic pressures. Central pulse pressure was more strongly related to all 3 arterial measures than was brachial pulse pressure ( $r=0.364$  versus  $0.309$  for plaque score;  $P<0.001$  for comparison of Spearman correlation coefficient;  $r=0.293$  versus  $0.249$  for intimal-medial thickness;  $P<0.002$ ;  $r=0.320$  versus  $0.289$  for vascular mass;  $P<0.05$ ). Among the 2403 participants free of clinical cardiovascular disease at baseline, 319 suffered fatal or nonfatal cardiovascular events during mean follow-up of  $4.8\pm 1.3$  years. After adjustment for age, gender, current smoking, body mass index, cholesterol:HDL ratio, creatinine, fibrinogen, diabetes, and heart rate, central pulse pressure predicted cardiovascular events more strongly than brachial pulse pressure (hazards ratio=1.15 per 10 mm Hg,  $\chi^2=13.4$ ,  $P<0.001$  versus hazards ratio=1.10,  $\chi^2=6.9$ ,  $P=0.008$ ). In conclusion, noninvasively-determined central pulse pressure is more strongly related to vascular hypertrophy, extent of atherosclerosis, and cardiovascular events than is brachial blood pressure. These findings support prospective examination of use of central blood pressure as a treatment target in future trials. (*Hypertension*. 2007;50:197-203.)

# Increased PWV predicts CV mortality (ESRD)

N = 305, 70 months follow up, Hypertension 2005;45:596

# Aortic Pulse Wave Velocity Is Associated With the Presence and Quantity of Coronary Artery Calcium

## A Community-Based Study

Iftikhar J. Kullo, Lawrence F. Bielak, Stephen T. Turner, Patrick F. Sheedy II, Patricia A. Peyser

**Abstract**—We investigated the relationship of aortic pulse wave velocity (aPWV), a measure of central arterial stiffness, with the presence and quantity of coronary artery calcium (CAC) in a community-based sample of adults without prior history of heart attack or stroke ( $n=401$ , mean age 59.8 years, 53% men). ECG-gated waveforms of the right carotid and right femoral artery were obtained by applanation tonometry, and aPWV was calculated using established methods. CAC was measured noninvasively by electron beam computed tomography, and CAC score was calculated. aPWV was significantly correlated with  $\log(\text{CAC} + 1)$ ;  $r=0.41$ ;  $P<0.0001$ ) and pulse pressure ( $r=0.47$ ;  $P<0.0001$ ). Multivariable logistic and linear regression models were used to identify independent predictors of the presence and quantity of CAC, respectively. In multivariable logistic regression analyses, aPWV was associated with the presence of CAC ( $P=0.011$ ) after adjustment for age, male sex, total cholesterol, high-density lipoprotein cholesterol, diabetes, history of smoking, systolic blood pressure, body mass index, and use of hypertension and statin medications. In multivariable linear regression analyses, aPWV was significantly associated with  $\log(\text{CAC} + 1)$  after adjustment for the covariates enumerated above ( $P<0.0001$ ). aPWV remained significantly associated with both the presence and quantity of CAC even after the additional adjustment for diastolic blood pressure. We conclude that aPWV is related to subclinical coronary atherosclerosis independent of conventional risk factors (including indices of blood pressure) and may be a biomarker of cardiovascular risk in asymptomatic individuals. (*Hypertension*. 2006;47:174-179.)

Arnold P.G. Hoeks, PhD; Monique M.B. Breteler, MD, PhD; Jacqueline C.M. Witteman, PhD

**Background**—Arterial stiffness has been associated with the risk of cardiovascular disease in selected groups of patients. We evaluated whether arterial stiffness is a predictor of coronary heart disease and stroke in a population-based study among apparently healthy subjects.

**Methods and Results**—The present study included 2835 subjects participating in the third examination phase of the Rotterdam Study. Arterial stiffness was measured as aortic pulse wave velocity and carotid distensibility. Cox proportional hazards regression analysis was performed to compute hazard ratios. During follow-up, 101 subjects developed coronary heart disease (mean follow-up period, 4.1 years), and 63 subjects developed a stroke (mean follow-up period, 3.2 years). The risk of cardiovascular disease increased with increasing aortic pulse wave velocity index. Hazard ratios and corresponding 95% CIs of coronary heart disease for subjects in the second and third tertiles of the aortic pulse wave velocity index compared with subjects in the reference category were 1.72 (0.91 to 3.24) and

**Conclusions** - Aortic pulse wave velocity is an independent predictor of coronary heart disease and stroke in apparently healthy subjects.  
(*Circulation*, 2006;113:657-663)

**Conclusions**—Aortic pulse wave velocity is an independent predictor of coronary heart disease and stroke in apparently healthy subjects. (*Circulation*, 2006;113:657-663.)

**Note: the cluster of three out of 5 risk factors among abdominal obesity, altered fasting plasma glucose, BP ≥ 130/85 mmHg, low HDL-cholesterol and high TG (as defined above) indicates the presence of metabolic syndrome**

## Box 6 Laboratory investigations

### Routine tests

- Fasting plasma glucose
- Serum total cholesterol
- Serum LDL-cholesterol
- Serum HDL-cholesterol
- Fasting serum triglycerides
- Serum potassium
- Serum uric acid
- Serum creatinine
- Estimated creatinine clearance (Cockcroft-Gault formula) or glomerular filtration rate (MDRD formula)
- Haemoglobin and haematocrit
- Urinalysis (complemented by microalbuminuria via dipstick test and microscopic examination)
- Electrocardiogram

### Recommended tests

- Echocardiogram
- Carotid ultrasound
- Quantitative proteinuria (if dipstick test positive)
- Ankle-brachial BP Index
- Fundoscopy
- Glucose tolerance test (if fasting plasma glucose >5.6 mmol/L (100 mg/dL))
- Home and 24 h ambulatory BP monitoring
- Pulse wave velocity measurement (where available)

### Extended evaluation (domain of the specialist)

- Further search for cerebral, cardiac, renal and vascular damage. Mandatory in complicated hypertension
- Search for secondary hypertension when suggested by history, physical examination or routine tests: measurement of renin, aldosterone, corticosteroids, catecholamines in plasma and/or urine; arteriographies; renal and adrenal ultrasound; computer-assisted tomography; magnetic resonance imaging

## Box 7 Position statement: Searching for sub-clinical organ damage

Due to the importance of subclinical organ damage as an intermediate stage in the continuum of vascular disease and as a determinant of total cardiovascular risk, signs of organ involvement should be sought carefully by appropriate techniques:

1. Heart – Electrocardiography should be part of all routine assessment of subjects with high BP in order to detect left ventricular hypertrophy, patterns of “strain”, ischaemia and arrhythmias. Echocardiography is recommended when a more sensitive detection of left ventricular hypertrophy is considered useful. Geometric patterns can be defined echocardiographically, of which concentric hypertrophy carries the worse prognosis. Diastolic dysfunction can be evaluated by transmitral Doppler.
2. Blood vessels – Ultrasound scanning of carotid arteries is recommended when detection of vascular hypertrophy or asymptomatic atherosclerosis is deemed useful. Large artery stiffening (leading to isolated systolic hypertension in the elderly) can be measured by pulse wave velocity. It might be more widely recommended if its availability were greater. A low ankle-brachial BP index signals advanced peripheral artery disease.
3. Kidney – Diagnosis of hypertension-related renal damage is based on a reduced renal function or an elevated urinary excretion of albumin. Estimation

**Table 3 High/Very high risk subjects**

- BP  $\geq$  180 mmHg systolic and/or  $\geq$  110 mmHg diastolic
- Systolic BP  $>$  160mmHg with low diastolic BP ( $<$ 70 mmHg)
- Diabetes mellitus
- Metabolic syndrome
- $\geq$  3 cardiovascular risk factors
- One or more of the following subclinical organ damages:
  - Electrocardiographic (particularly with strain) or echocardiographic (particularly concentric) left ventricular hypertrophy
  - Ultrasound evidence of carotid artery wall thickening or plaque
  - Increased arterial stiffness
  - Moderate increase in serum creatinine
  - Reduced estimated glomerular filtration rate or creatinine clearance
  - Microalbuminuria or proteinuria
- Established cardiovascular or renal disease

**Table 4 Availability, prognostic value and cost of some markers of organ damage (scored from 0 to 4 pluses)**

Markers	CV predictive value	Availability	Cost
Electrocardiography	++	++++	+
Echocardiography	+++	+++	++

<b>PWVao (m/s)</b>	10,0	2,2	5,6	17,1
<b>Carotis positive (%)</b>	319 (49,6)			
<b>Carotis negative (%)</b>	324 (50,4)			

# Carotis protocol

Both extracranial carotis systems were screened completely.

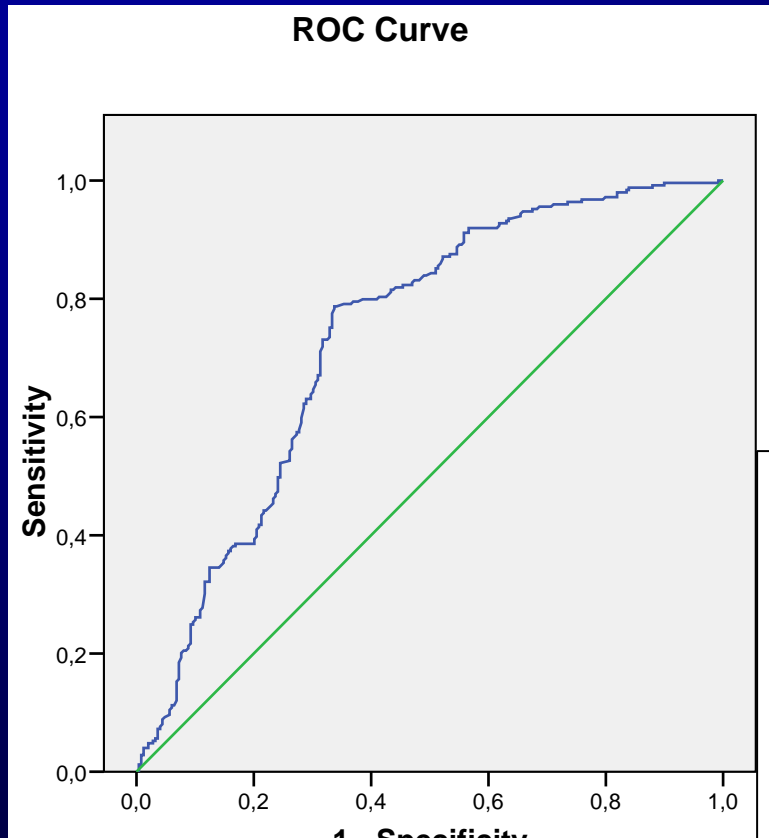

**The results were considered to be positive for asymptomatic atherosclerosis if**

- $\geq 1$  mm echogenic (calcificated) plaque was seen  
and/or
- $\geq 1,3$  mm IMT was measured

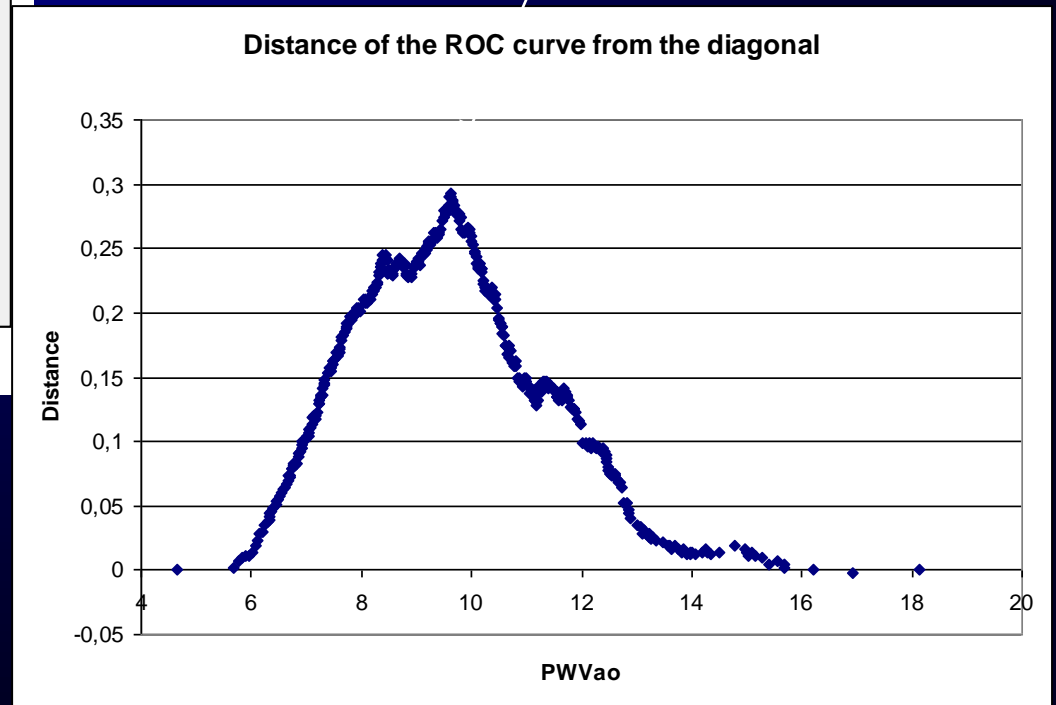

# Arterial stiffness (PWVao) protocol

- A new, validated, oscillometric, user independent device (Arteriograph) was used, which can perform a complete arterial function analysis within 3 minutes with a single upper arm cuff.
- The measurements were independent from the user
- The patients had at least 10 minutes rest before the examination
- Caffeine intake, smoking was not allowed 3 hours before of the measurement
- Alcohol intake was not allowed 10 hours before of the examination
- Patients with arrhythmia and nitrate use were excluded

# Results – PWVao threshold

The optimal threshold of PWVao proved to be **9,62** m/s with ROC

# Results

## Asymptomatic Population

	<u>Overall</u>	<u>Male</u>	<u>Female</u>
Sensitivity (%)	76,5	68,1	84,9
Specificity (%)	64,5	79,7	55,5
P. pred. value (%)	68,0	73,6	65,2
N. pred. value (%)	73,6	68,5	78,9
Relative Risk*	2,6	2,4	3,1
Odds ratio**	6,0	6,8	7,0

\*Relative Risk shows that among patients with high (>9,62 m/s) PWVao, how many times more probable the disease (e.g. carotis atherosclerosis) than with low PWVao subjects

\*\*Odds ratio shows that how many times higher the chance to diagnose the disease (e.g. carotis atherosclerosis) properly, than improperly

**The prevalence of carotid atherosclerosis was 49% in the studied population**

Examination date and time: 12.01.2006. 09:45 JUG-SY: 58 cm

Operator's name: ARTERIOGRAM

Sys: 157 mmHg Dia: 94 mmHg HR: 68 /min MAP: 115 mmHg PP: 63 mmHg

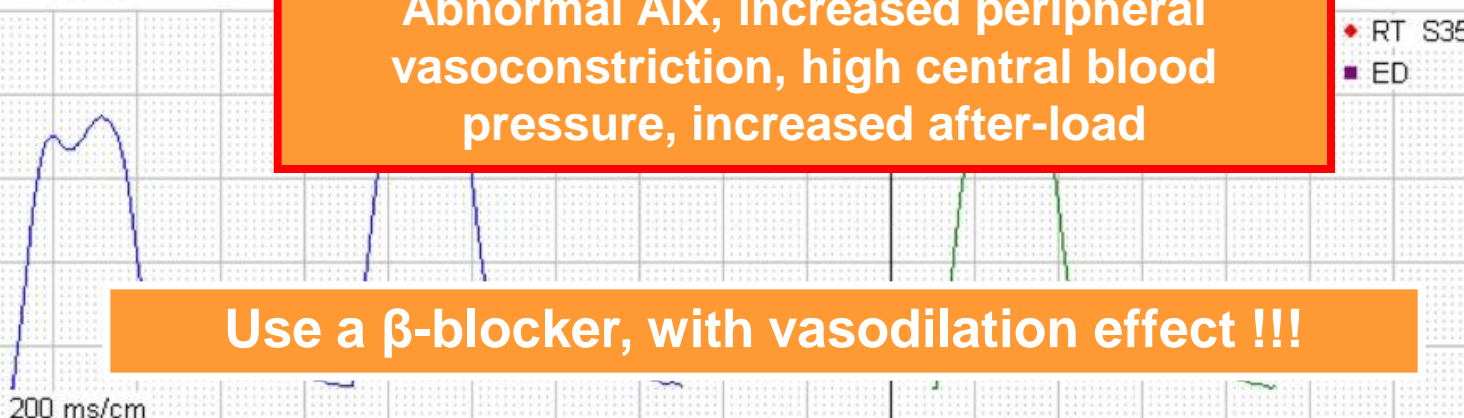

### Results S 35

Aix brachial: 9.07 % ED: 345 ms PWVao: 12.00 m/s SBPao: 160.05 mmHg

Aix aortic: 36.4 %

**Abnormal Aix, increased peripheral vasoconstriction, high central blood pressure, increased after-load**

**Use a β-blocker, with vasodilation effect !!!**

# TensioMed™ Arteriograph

## Arterial Stiffness Report

### Patient details

Name:

Date of Birth: 07.10.1938. Height: 167 cm BMI: 29.40 Cholesterol: 3.90 mmol/l

Sex: Female Weight: 82 kg

Comment:

Nebivolol

10 year risk of fatal CVD (EHRC score): 3% (medium risk)

The same subject with modified therapy

β-blocker with vasodilation effect

### Study data

Examination date and time: 29.11.2006. 13:45 JUG-SY: 54 cm

Operator's name: ARTERIOGRAM

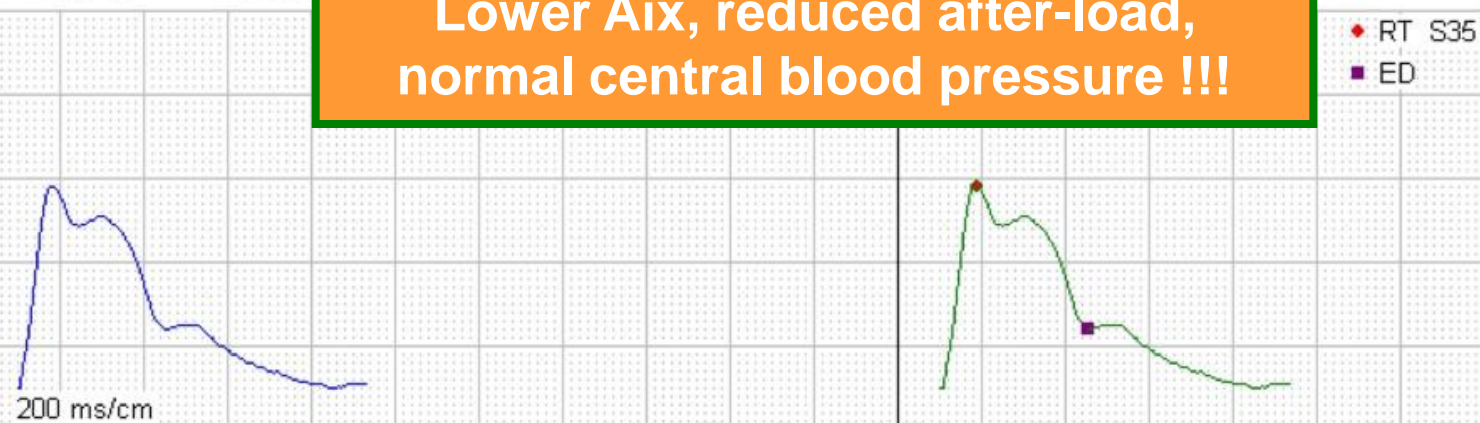

Sys: 141 mmHg Dia: 77 mmHg HR: 70 /min MAP: 98 mmHg PP: 64 mmHg

### Results S 35

Aix brachial: -15.03 % ED: 355 ms PWVao: 9.80 m/s SBPao: 134.81 mmHg

Aix aortic: 26.20 %

Lower Aix, reduced after-load,  
normal central blood pressure !!!

# INDICATIONS OF MEASURING ARTERIAL FUNCTION

**TO SCREEN FOR EARLY ATHEROSCLEROSIS AMONG  
ASYMPTOMATIC, APPARENTLY „HEALTHY” SUBJECTS  
FOR IMPROVING CV RISK ASSESSMENT**

**AND**

**TO ASSESS THE EFFECT OF THE THERAPY ON  
VASCULAR FUNCTION AMONG PATIENTS WHERE  
ATHEROSCLEROSIS HAS BEEN ESTABLISHED  
(CAD, POST MI, STROKE, PAD)**

**THE METHOD CAN NOT BE USED FOR DETECTING  
LOCAL STENOSIS IN A CERTAIN ARTERY !**
